## 1 Introduction

In specifications [1] applicable for Global B programs and [2] applicable for Global A programs General Motors (GM) introduces the possibility to use compression for the ECU flash programming process. Both specifications allow for different compression algorithms to be used. The default algorithm GM specifies is the ARLE (Adaptive Run Length Encoding) compression which is variant of RLE (Run Length Encoding).

GM will create the Signed- and Compressed data containers, therefore their tooling need to be able the required compression.

### Download Container Creation GM Part (Signed & Compressed)

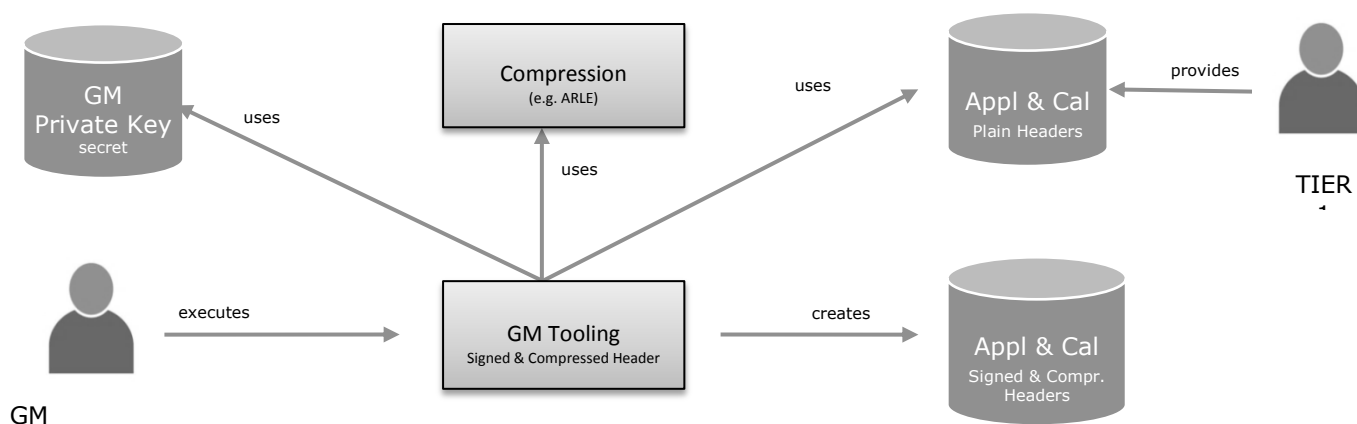

Figure 1-1 Gm creates signed- and compressed container format out of provided plain format.

## 2 Vector compression related products and services

Within our deliveries since 2015 (one in late 2014) we support compression in our GM SLP5 and SLP6 products as defined in [1] or [2].

As per January 2015 you can choose between these options:

1. Fully integrated support of the GM specified ARLE Algorithm
2. Compression Interface, to be used to implement user specific compression as required by GM

This document shall explain the used API for 1. and provide the required information to implement a user specific compression for 2.

---

**Note**

The Vector Standard compression ( LZSS based ) is currently not available for the GM compression use case. It is left open, if GM can use it in their tooling to create containers in the future. Please contact us to get latest information on this.

---

### 3 The Vector Data Processing API

Every compression to be implemented will have to be below the Data Processing API found in `fb_l_ap.c`. Each function is called with a pointer to a `tProcParam` structure with the following members; some are input and some are output, `dataLength` is both input and output:

Struct <code>tProcParam</code>	
<code>dataBuffer</code>	<b>Input:</b> data buffer with to be decompressed byte stream.
<code>dataLength</code>	<b>Input:</b> Length of provided input data, <b>Output:</b> Length of consumed input data
<code>dataOutBuffer</code>	<b>Output:</b> Buffer provided for output data. Only modify contents, but not pointer
<code>dataOutLength</code>	<b>Output:</b> Length of produced output data
<code>dataOutMaxLength</code>	<b>Input:</b> Maximum length of output data (size of buffer provided for output data)
<code>wdTriggerFct</code>	<b>Input:</b> Watchdog trigger function / Polling function; to be called at least every 1ms within decompression.
<code>mode</code>	

Table 3-1 `tProcParam` members and their function

Prototype	
<code>tFblResult ApplFblInitDataProcessing( tProcParam * procParam )</code>	
Parameter	
<code>tProcParam * procParam</code>	Check member Table 3-1. Relevant parameter for Init is <code>procParam-&gt;mode</code> .
Return code	
<code>tFblResult</code>	<code>kFblOk</code> / <code>kFblFailed</code> upon function execution success.
Functional Description	
Call Compression initialization function if applicable (default on any compression: <code>( MODULE_DF_COMPR == (procParam-&gt;mode &amp; MODULE_DF_COMPR) )</code> ).	
Particularities and Limitations	
<p>&gt; Is called on reception of a new data segment. Usually left empty for Gm compression (Not required in case of ARLE, might be helpful in case of user decompression).</p>	

Call context	
>	Called from fbl_hdr.c FblHdrCheckEnvelopesExtractSignedHeader during envelope extraction
>	Called from fbl_mem.c FblMemSegmentStartIndication before programming data Segment

Table 3-2 Function ApplFblInitDataProcessing

Prototype	
<code>tFblResult ApplFblDataProcessing( tProcParam * procParam )</code>	
Parameter	
<code>tProcParam * procParam</code>	Check member table Table 3-1.All members are used
Return code	
<code>tFblResult</code>	kFblOk/kFblFailed depending on function success.
Functional Description	
<p>Prepares and calls Decompress functionality, if compression is applicable through <code>procParam-&gt;mode</code></p> <ul style="list-style-type: none"> <li>- Redefines <code>procParam-&gt;dataOutMaxLength</code> depending on left bytes in segment in case of decompression of programmed data.</li> <li>- Consumes Segment size in case of decompression of programmed data</li> </ul>	
Particularities and Limitations	
> Already prepared for Compression use both for ARLE and user specific compression	
Call context	
<p>Called from fbl_hdr.c FblHdrCheckEnvelopesExtractSignedHeader during envelope extraction</p> <p>Called from fbl_mem.c FblMemProcessJob during programming.</p>	

Table 3-3 Function ApplFblDataProcessing

Prototype	
<code>tFblResult ApplFblDeinitDataProcessing( tProcParam * procParam )</code>	
Parameter	
<code>tProcParam * procParam</code>	Check member table in Table 3-1. All members are used
Return code	
<code>tFblResult</code>	kFblOk/kFblFailed depending on function success.
Functional Description	

Particularities and Limitations
> May call Decompression Deinit if applicable (not required in case of ARLE, might be helpful in case of user decompression)
Call context
> Blind text, blind text

Table 3-4    Function ApplFblDeinitDataProcessing

## 4 Particularities on the GM use case

### 4.1 Compression indicator

GM does not use the UDS commonly used DFI of service \$34 to determine if decompression is applicable.

Instead, on the first \$36 received for a given module, the module's envelope is analyzed to determine the availability of a compression envelope. If such an envelope is found the decompression is applicable for this module (compare [1] or [2], chapter "Assigned Data Types" and "Signed and Compressed Application / Calibration File").

If decompression is applicable, decompression need to be performed two times:

- > First decompressing the signed header to FblRamHeader. This allows for analyzing the signed header envelope in RAM
- > Decompressing to be programmed content behind the signed header, starting with the plain header envelope. To do this the decompression need to start again from the first compressed byte, but shall produce output bytes only when the first to be programmed byte is reached.

Each time the Compression Init function (ApplFblCmprInit(), mapped to CmprArleInit() in case of Vector solution) is called again from needs to be called again.

### 4.2 The mode flag

The procParam->mode flag can be used to query the context of the current decompression action mentioned above:

condition	Decompression context
procParam->mode == MODULE_DF_COMPR_HDR	Decompression of the signed header to FblRamHeader
procParam->mode == MODULE_DF_COMPR	Decompression the to be programmed content
((procParam->mode & MODULE_DF_COMPR) == MODULE_DF_COMPR)	Any Decompression (Signed header or programmed content)

Table 4-1 Two different Decompression states: procParam->mode

### 4.3 Decompress Signed header to Ram

In fbl\_hdr.c the function FblHdrCheckEnvelopesExtractSignedHeader will call the whole Data Processing Api once (ApplFblInitDataProcessing/ ApplFblInitDataProcessing / ApplFblDeinitDataProcessing) in order to decompress enough bytes to be able to extract the Signed Header envelope completely.

### 4.4 Decompression of Programmed Data

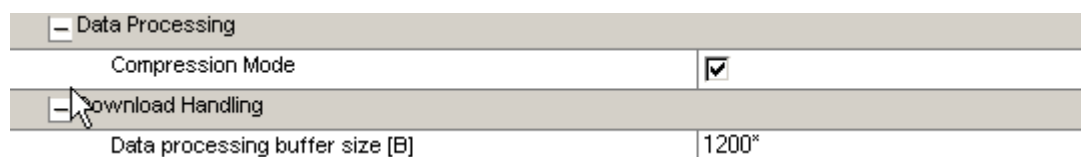

Initiated from fbl\_hdr.c FblHdrTransferDataProcess->FblMemDataIndication() (fbl\_mem.c) the programmed data is decompressed. The decompression once again start from the

very first compressed byte. However, the decompression will receive a **threshold** value, in order to decide which are the first bytes to produce as output (the first to be programmed bytes after the signed header envelope and the plain header data type bytes).

#### 4.5 GENy configuration

Be sure enable “Compression Mode” in GENy FblDrCan\_XX module. Data processing size need to be configured to be large enough to hold the complete header (fbl\_hdr.h HDR\_MODULE\_MAX\_RAW\_LEN). For ARLE this is 936 bytes when allowing a maximum number of data regions (Maximum Number of Segments, GENy configured) of 10.

The Software will check the configured number of bytes to be large enough.

Data Processing	
Compression Mode	<input checked="" type="checkbox"/>
Download Handling	
Data processing buffer size [B]	1200*

Figure 4-1 GENy configuration compression

## 5 The compression module (user compression: to be created)

In the case you receive a fully integrated compression this is already provided. In case you want to implement a user specific compression you have to create this module.

### 5.1 Files

File Name	Description
cmpr.c	Decompression source code
cmpr.h	Decompression header file

Table 5-1 Files (Provided with ARLE, to be created for user specific compression)

### 5.2 Configuration

No configuration is required in case of the provided ARLE modules. There are no special requirements for your user specific compression configurations.

### 5.3 The API

Find below the functions and Global required for the compression interface. The interface is already implemented if you ordered a fully integration compression. If you want to implement a user specific compression, you need to implement the functions for your compression algorithm.

In fbl:ap.c the required API is mapped to the used naming scheme, adapt the names to your required scheme (CmprXXDecompress, CmprXXInit, CmprXXReadCmprHeader):

```
#if defined( FBL_ENABLE_COMPRESSION_MODE )
/* The below functions are defined if you ordered the Vector Compression interface,
 * the interface has to be implemented by you else.
 */
#include "cmpr.h"
#define ApplFblDecompress CmprArleDecompress
#define ApplFblCmprInit CmprArleInit
#define ApplFblCmprReadHeader CmprArleReadCmprHeader
#endif
```

Prototype	
<code>tFblResult CmprXXInit(void)</code>	
Parameter	
-	-
Return code	
<code>tFblResult</code>	kFblOk/kFblFailed depending on function success.
Functional Description	
Initialize compression module.	
Particularities and Limitations	
> None	
Call context	
Called from <code>fbl_hdr.c</code> upon start of decompression (two times, once for decompression of header, another time for decompression of to be programmed data).	

Table 5-2 Function CmprXXInit

Prototype	
<code>tFblResult CmprXXDecompress( tProcParam* procParam, uint16 outThreshold);</code>	
Parameter	
<code>tProcParam* procParam</code>	Check member table Table 3-1. All members are used (compare Particularities and Limitations).
<code>outThreshold</code>	Put data to <code>procParam-&gt;dataOutBuffer</code> only after a certain amount of decompressed bytes. A value of "0" means no threshold is used.
Return code	
-	-
Functional Description	
Decompress data stream according to either Gm defined ARLE or user specific compression (in accordance with GM specification).	
Particularities and Limitations	
<ul style="list-style-type: none"> <li>&gt; Should be callable with less input bytes than required. May need to backup partly decompressed bytes from current decompression action waiting for required compressed input bytes (compare Arle example state machine <a href="#">Figure 5-1</a>)</li> <li>&gt; Always fill the maximum requested data output (<code>dataOutMaxLength</code>) and thus allow for partly decompression, if provided buffer is not large enough to do a full decompression (compare Arle example state machine <a href="#">Figure 5-1</a> below).</li> <li>&gt; The Compression module needs to call <code>procParam -&gt; wdTriggerFct</code> at least every 1ms (Recommendation in all loops) to guarantee correct handling of timer related functionality in the Fbl (despite the member name it is more the only watchdog)</li> </ul>	

**Call context**

Called from fbl\_ap.c data processing interface, App1FblDataProcessing()

Table 5-3 Function CmprXXDecompress

Prototype	
<pre>tFblResult CmprXXReadCmprHeader( tFblLength* comprLength, const vuint8 * cmprBuffer, vuint16 * cmprDataOffset)</pre>	
Parameter	
tFblLength* comprLength	Output: the compressed data size (return 0 if not applicable for user specific DataInfo)
const vuint8 * cmprBuffer	Input: Pointer to compressed data
vuint16 * cmprDataOffset	Output: Index to start of compressed data stream (0 if no DataInfo field used)
Return code	
-	-
Functional Description	
<p>Read Compression header DataInfo field/format (compare [1] or [2] “Details of a Compressed and Signed file”) . In case of ARLE this header includes information of the compressed data length.</p>	
Particularities and Limitations	
<p>&gt; Check [1] or [2] on Compression header requirements.</p>	
Call context	
<p>&gt; Called from FblHdrCheckEnvelopesExtractSignedHeader when compressed envelope has been identified.</p>	

Table 5-4 Function CmprXXReadCmprHeader

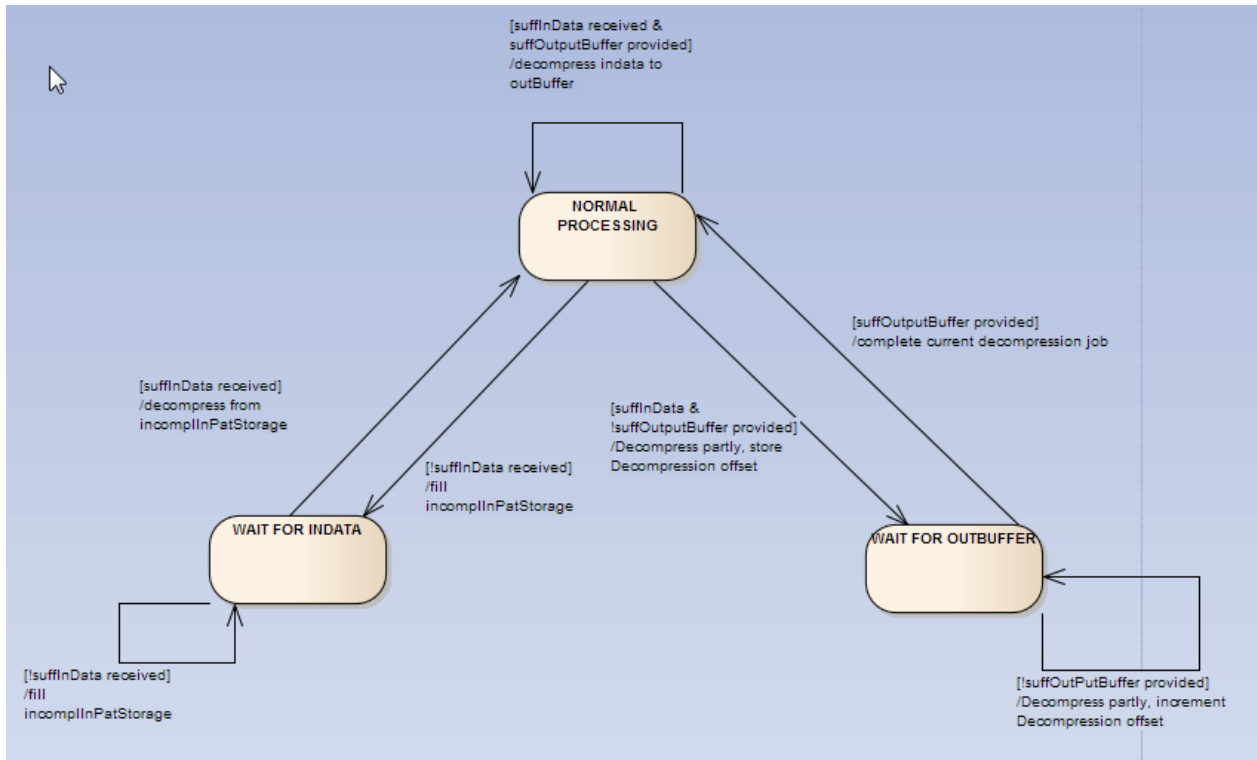

Figure 5-1 Arle Decompression State machine fulfilling interface requirements: Allow reception of incomplete Pattern; allow partly decompression

## 6 Glossary and Abbreviations

### 6.1 Glossary

Term	Description
GM	General Motors Company
ECU	Electronic Control Unit
FBL	Flash Boot Loader
LZSS Algorithm	Lempel-Ziv-Storer-Szymanski-Algorithm
UDS	Unified Diagnostic Services
GMLAN	General Motor Local Area Network
DFI	Data Format Identifier
\$34	UDS/GMLAN request download service
\$36	UDS/GMLAN Transfer Data service

### 6.2 Abbreviations

Abbreviation	Description
ARLE	Adaptive Run Length Encoding
RLE	Run Length Encoding
